## 1.进程创建

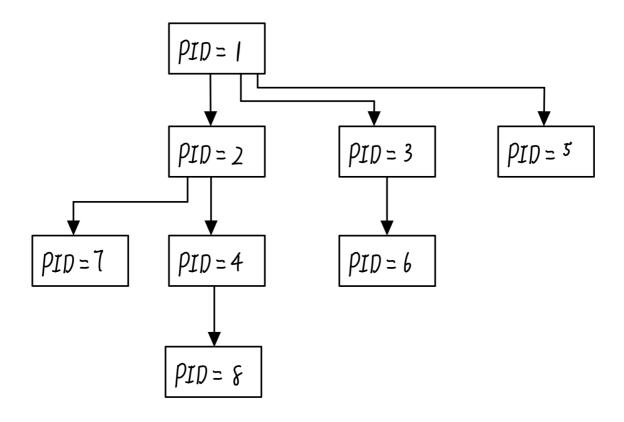

```
#include <stdio.h>
#include <unistd.h>
#include <sys/wait.h>
#include <stdlib.h>
int main() {
   pid_t pid;
    for (i = 0; i < 3; ++i) {
       pid = fork();// fork another process
       if (pid < 0) \{ // error occurred
           fprintf(stderr, "Fork Failed");
           exit(-1);
       } else if (pid == 0) {
           fprintf(stdout, "i=%d, pid=%d, parent pid=%d\n", i, getpid(),
getppid());
       }
        wait(NULL);
       exit(0);
}
```

请问该程序最终一共生成几个进程?假设当前进程 PID 为 1,生成的进程 PID 依次加 1,请将生成进程 关系图画出来。

## 运行结果为:

```
i=0, pid=17296, parent pid=17295
i=1, pid=17297, parent pid=17295
i=2, pid=17298, parent pid=17295
i=1, pid=17299, parent pid=17296
i=2, pid=17300, parent pid=17297
i=2, pid=17301, parent pid=17296
i=2, pid=17302, parent pid=17299
```

故共创建出7个线程,其关系如下

## 2、程序题

程序题)写一个 2 线程的程序,首先生成一个从 1 到 1000 万的整数数组, 然 后用两个线程分别计算数组奇数部分和偶数部分的和,并打印出总的和。分别 在单核和双核系统上运行该程序,计算加速比。(采用 pthread API) 提示:单核和 双核可在虚拟机上配置;pthread 调用方法网上有大量资料,比如 <a href="https://www.ibm.com/developerworks/cn/linux/thread/posix\_thread1/inde">https://www.ibm.com/developerworks/cn/linux/thread/posix\_thread1/inde</a> x.html

```
#include <stdio.h>
#include <stdlib.h>
#include <pthread.h>
#define MAXLENGTH 10000000
//int pthread_create(pthread_t * tid, const pthread_attr_t * attr, void * ( * func) (void * ), void * arg)
//int pthread_join (pthread_t tid, void ** status);
int data[MAXLENGTH];
int cnt = 100;
void *sum(void *input);
unsigned long long res = 0;
int main() {
    while (cnt--){
       unsigned long long *odd, *even;
        pthread_t mythread;
        for (int i = 0; i < MAXLENGTH; ++i) {
            data[i] = i + 1;
        //created thread
```

```
pthread_create(&mythread, NULL, sum, (void*)0);
        pthread_join(mythread, (void **)&odd);
        //currunt thread
        even = sum((void *)1);
        * pthread_create(&mythread, NULL, sum, (void*)1);
         * pthread_join(mythread, (void **)&even);
        res = *even + *odd;
        free(odd);
       free(even);
    }
    printf("%llu\n", res);
   return 0;
void *sum(void *input){
   int i = (unsigned long long )input;
    unsigned long long *res = malloc(sizeof (unsigned int));
    for ( *res = 0; i < MAXLENGTH; i = i + 2) {
       *res += data[i];
   }
    return res;
}
```

可以注意到有一部分代码被注释掉了,第一次写的时候创建了两个线程,但我没有意识到在程序正在运行时就已经是一个currunt thread了,换言之这相当于写了一个三线程程序,最后产生的结果是灾难性的,因为甚至出现了单核运行时间低于双核运行时间的情形。在作出适当修改后,结论如下:

双核对单核的加速比为:

$$\frac{T_m}{T_s} = \frac{3.744}{3.643} = 1.027$$

```
stu@stu:-/OShomo$ time ./thread 50000005000000 
real 0m3.744s 
user 0m3.716s 
sys 0m0.020s
```

```
stu@stu:~/OShomo$ time ./thread 50000005000000 real 0m3.643s user 0m3.625s sys 0m0.024s
```

```
stu@stu:~/OShomo$ time ./thread1
50000005000000

real 0m3.693s
user 0m3.682s
sys 0m0.004s
```

stu@stu:~/OShomo\$ time ./thread1 500000050000000

real 0m3.675s user 0m3.651s sys 0m0.016s
